

Networking Layer & API Contracts

The infrastructure is strategically designed to shift seamlessly from mock simulations to production-ready network streaming without refactoring higher-level architectures:

1. **API Contracts (YAML):** Comprehensive contract definitions—including formal resource paths, HTTP methods, structured application Request representations, and Response schemas—are completely isolated under `/contracts/tickets-api.yaml`.
2. **ApiService:** A dedicated Retrofit declaration file mirroring all operations outlined in the YAML specs.
3. **RetrofitClient:** A centralized singleton providing pre-configured `OkHttpClient` interceptors and JSON deserialization tooling (`GsonConverterFactory`).
4. **Future Migration:** The application components currently access `MockTickets` inside the repository implementations. Moving the app to a real backend requires swapping the local simulation calls for network calls via `apiService`, requiring zero rewrites on the UI or `ViewModel` blocks.
