

System General Flow

The application operates under a Unidirectional Data Flow (UDF) and reactive principles to keep data synchronized without manual screen reloads:

1. **Authentication:** The user logs in via LoginScreen. Credentials are processed by AuthRepository to initialize the active AuthSession.
2. **Data Fetching & Subscription:** Upon entering TicketListScreen, the TicketListViewModel automatically subscribes to the asynchronous flow exposed by TicketRepository. The repository fetches data from the Mock layer and emits it downstream.
3. **Mutation Actions:** When a user interacts with the system—such as creating a ticket in CreateTicketScreen or shifting priorities in TicketDetailScreen—the event triggers a method inside the respective ViewModel, which delegates the write operation to the TicketRepository.
4. **Reactive Propagation:** The repository modifies its internal state, forcing an immediate automatic emission through the StateFlow. All active collectors (screens and viewmodels) receive the update instantly, causing Jetpack Compose to recompose only the affected UI components.
