

Technical Justification

What problems do these strategies solve?

- **StateFlow (Event-Driven Communication):** Eliminates rigid interface-to-interface coupling and stale data issues. Instead of passing intents back and forth or forcing manual view invalidations, components simply observe a stream. This completely solves multi-screen data discrepancy.
- **Feature Flags:** Solves deployment blocks and provides internal control. Testing complex modules or hiding unstable views can be performed instantly on runtime configurations without writing conditional hacks across various UI components or building separate application variants.

Why were they selected?

These architectural strategies were selected because they deliver an optimal balance between low complexity and high maintainability. They leverage native, recommended Kotlin toolsets (StateFlow) to satisfy enterprise requirements without over-engineering the application structure with complex third-party frameworks—fully respecting the project's timeline and budget constraints.
